Newer Modalities for repeated IVF Failure Patients

Intracytoplasmic Sperm Injection (ICSI) is a part of the IVF treatment and it is indicated when the sperm quality is not good and not capable of fertilizing the egg. In ICSI, a single best quality sperm is selected under high magnification of 600x and it is injected into the egg using a small needle. This procedure is helpful for male patients

with low sperm count and motility.

Intracytoplasmic Morphologically selected Sperm Injection (IMSI) is a variation of ICSI where the sperm selection procedure is more advanced and done under very high magnification of 6000x. The selected sperm is injection into egg. This procedure is helpful for male patients with abnormal sperms.

Laser assisted hatching system which augments the success rates significantly by improving the implantation rates. This technique helps the blastocyst to hatch in time, by which the implantation potential is improved, where

embryos have thicker *zona pellucida* and for cryopreserved Blastocyst/ Embryos too. In Laser assisted hatching, a laser beam is used to thin the zone pellucida (outer shell) of the embryo before it is transferred into the uterus. This outer shell is believed to become thicker and hardened with aging of the oocytes (egg).

The **Embryoscope** is an incubator that maintain the necessary physiological condition required by a living embryo while they are in the IVF Laboratory. It has an incorporated time lapse system that has a camera that continuously captures images and records them as a video of the embryonic development.
